

## Direct Seeding of Rice

### Why in news?

Recently, the Punjab government has been actively promoting the direct seeding of rice (DSR).

### What is direct seeding of rice (DSR)?

- **Definition** - It is a planting method that involves directly sowing of seeds in the field.
- It requires no nursery preparation or transplantation.
- **Need of DSR** - The conventional transplanting method require intense labour, continuous flooding of water and takes higher time and labour resources.

### Transplanting Method of Rice

- It is a planting method that involves the planting of seedlings or whole plants in the field or garden.
- **Requirement** - seed germination may occur inside the greenhouse.
- **Advantages** - Weed management is easier and it requires less amount of seeds.
- **Disadvantages** - Slower maturation of crops.
- It is expensive in comparing to DSR.
- It require more usage of water and thereby affecting the ground water table.

- **Requirements** - Soil suitability is crucial for the successful implementation of DSR.
- **Soil texture** - DSR should be avoided in light-textured soils as they do not retain water well.
- It is more suitable for heavy or medium-to-heavy-textured soils which contains more clay and less sand, whereas light-textured soils have less clay and more sand.
- **Iron content** - Soil with severe iron deficiency, and weed problems must not be cultivated using this technique.
- Even medium-textured soils are unsuitable simply due to their lack of iron.
- In case iron supplements are being used, farmers should apply ferric iron, which is green-coloured and not oxidised, rather than oxidised iron, which is brown in colour.
- Lack of iron content can severely impact yields and lead to major financial losses for farmers.

### What is tar-wattar technique?

- **Sowing of seeds** - The paddy seeds are directly sown, roughly 20-30 days prior to when they would have been transplanted.
- **Soil levelling** - The field is irrigated and laser leveled prior to the seeding process which is carried out using a seed drill or lucky seeder.
- **Seed treatment** - The seeds soaked in a fungicide solution for eight hours, then dried for half a day before sowing.

- **Irrigation** - The first round of irrigation is carried out 21 days after sowing, followed by 14-17 more rounds at 7-10 day intervals, depending on soil type and the quality of the monsoon.
- The final irrigation takes place 10 days before harvest.
- The traditional method requires 25-27 irrigations in total.

## What are benefits of DSR?

- **Saves water** - This can reduce water use by 15% to 20% (the traditional puddling method requires 3,600 to 4,125 litres of water to grow a single kilo of rice).
- **Saves labour** - DSR requires less labour and matures 7 to 10 days faster.
- **Ground water recharge** - DSR offers avenues for ground water recharge as it prevent the development of hard crust just beneath the plough layer due to puddled transplanting.
- Straw management - It matures 7-10 days earlier than puddle transplanted crop, therefore giving more time for management of paddy straw.
- **Higher yield** - Research results have also indicated that yield, after DSR, are one to two quintals per acre higher than puddled transplanted rice.
- **Environment benefits** - It leads to lower GHG emissions.
- **Labour welfare** - Mechanized DSR provides employment opportunities for youth through service provision business model
- It increases total income by reducing cost of cultivation.

## What are the major challenges associated with DSR?

- **Irrational use** - In the race to avail the government incentives, some farmers use DSR in unsuitable soils, leading to the need for irrigation every second or third day.
- This completely counteracts the water-saving benefits of DSR, and in fact, ends up guzzling down more water.
- **Less soil availability** - Only 20% of Punjab's soil is light-textured.
- **Lack of iron content** - It should not be cultivated in sandy and loamy sand as these soils suffer from severe iron deficiency, and there is higher weed problem in it.
- **Higher seed rates** - Seed monopoly automatically the price of seeds thereby reducing the income prospects for farmers.
- **Seeds exposed to birds and pests** - Direct seeding increases the vulnerability of seed to get targeted by the pests and birds.
- **Weed management** - There is higher growth of unsuitable plants in the DSR fields which compete the paddy crops and thereby reduce the yield.
- **Herbicide intolerance** - While herbicide needs to be sprayed to control the weeds, irrational use make the crops intolerant to herbicide.

## What lies ahead?

- **Awareness drive** - A basic lack of awareness and understanding is holding DSR back.
- Thus, awareness should be created for rational use of DSR.
- **Educating farmers** - Extensive training and a ready helpline be provided, to handhold the farmers through the whole process, from pre-sowing to harvesting.
- This can instill confidence among farmers regarding DSR's efficacy.
