

## Lenacapavir

### Why in the news?

*Yearly HIV prevention injection shows promise in clinical trials.*

- Lenacapavir is an investigational anti-retroviral drug developed by Gilead Sciences.
- **Approved by** - U.S. Food and Drug Administration (FDA).
- It acts as a long-acting **HIV treatment and prevention drug** designed to be administered as an injection.
- **Administration and Dosage** - Lenacapavir is available in two forms
  - **Subcutaneous Injection** (Twice a Year)
  - **Intramuscular Injection** (Once a Year - Under Trial)
- **Working** - Lenacapavir is a capsid inhibitor, that targets the HIV-1 capsid, a protein shell that protects the virus's genetic material.
- By interfering with the capsid's function, it prevents HIV from replicating and infecting new cells.
- Unlike most HIV drugs that target enzymes (like reverse transcriptase or protease), Lenacapavir disrupts multiple stages of the viral life cycle, making it a unique and effective approach.
- The yearly version aims to provide long-term HIV prevention, making it more convenient than daily PrEP pills.
- **Current Status** - The Phase 1 trial for yearly prevention showed promising results, but larger studies are needed.
- A twice-a-year version for treatment has already shown success in Phase 3 trials.

*Currently, there is no cure or vaccine approved for HIV/AIDS.*
